# sSRyB calibration

---

Indicator-based  
approach

30/03/2023

**Cristian Perales and Barbara  
Jarmulska (DG-MF/MAP)**

# Motivation

- Construct and RRE-index that could be used together with other approaches to guide future activation and calibration of the sSyRB for RRE related risks
- Early warning models (EWM) can be used to detect vulnerable state pre-RRE-related systemic banking crises:
  - Identify top-performing indicators
  - Aggregate chosen indicators into an index for RRE risk (like SRI for cyclical risk)
- Purposes:
  - Provide information complimentary to SRI regarding the build-up of RRE vulnerabilities
  - Together with other approaches, could inform policy recommendations in the MPR and the ECB's tasks under Article 5 SSMR
  - Basis for external communication following ECB decisions

=> The purpose of this presentation is to present the data, approach, provide early work in progress results and collect feedback

# Literature

- Early warning models – rich literature using discrete dependent variable models, among others:
  - Barrell et al. (2010) used logit models to signal systemic banking crises
  - Demirgüç-Kunt and Detragiache (2005) used both the signalling approach and discrete dependent variable models to predict banking crises and to analyse their determinants
  - Lo Duca and Peltonen (2013), using discrete dependent variable models aimed at signalling systemic financial crises, showed that vulnerabilities build up non-linearly
  - Bruns and Poghosyan (2016) used a logit model aggregation, called extreme bound analysis, to signal fiscal stress events
- Most relevant references:
  - Ferrari, Cornacchia, Pirovano (2015) provide a formal statistical evaluation of potential early warning indicators for real-estate related banking crises – and highlight the important role of both real estate price variables and credit developments
  - Lang, Izzo, Fahr and Ruzicka (2019) propose a domestic cyclical systemic risk indicator capturing risks from domestic credit, real estate markets, asset prices, and external imbalances

# Model used for the identification of early warning

We consider the following discrete choice (logit) model:

$$\Pr(y_{i,t} = 1 | \alpha, X_{K,i,t}) = F(\alpha + X'_{K,i,t}\beta_K)$$

- $y_{i,t}$  denotes our response variable (taking the value 1 for observations 12 to 5 quarters before the real estate crises and 0 otherwise)
- $i$  stands for country
- $X'_{K,i,t}$  explanatory variables including a constant term
- $F(\bullet)$  represents a logistic function of the form  $F(z) = (1 + e^{-z})^{-1}$
- We use robust standard errors

# LHS crisis variable

- RRE-related crisis as identified in Ferrari, Cornacchia, Pirovano (2015) complemented with information from ESRB crisis database → 15 crisis events in EU countries and UK

## Vulnerable state pre-RRE-related systemic banking crises

(number of countries in a vulnerable state at a given time)

- The dependent variable of the logit model is the vulnerable state pre-RRE-related systemic banking crises, defined as 12-5 quarters before a crisis event
- Dependent variable is set to missing during a systemic crisis
- If we could start the sample in 1980s, we would have 15 observations, 1/3 of them pre-global financial crisis (for the moment we only use 7 observations in the multivariate regression – further details later)

# RHS variables (I/II)

- Following the literature and expert judgment, we consider variables on credit developments, debt burdens, house prices (dynamics and overvaluation), real estate and construction activity and we divide them into following categories:
  - Structural credit and debt burden (levels)
  - Cyclical credit and debt burdens (changes)
  - RRE prices
  - Construction/real estate investment
- Following Lang et al (2019), we consider the following transformations of variables:
  - 1 quarter, 1 year, 2-year and 3-year changes in percentage points
  - 1 quarter, 1 year, 2-year and 3-year growth rates
  - Gaps
- Putting together the raw variables and their transformations, we initially considered more than 100 variables in the univariate setting – after we exclude variable that are not available for any crisis in the 90s or not available for several countries we arrive at ca. 70 for the univariate analysis

# RHS variables (II/II)

| Variables                                                    | Transformations                                                   |
|--------------------------------------------------------------|-------------------------------------------------------------------|
| Credit to NFPS as % GDP                                      | 1 quarter, 1 year, 2-year and 3-year changes in percentage points |
| Credit to NFPS                                               | 1 quarter, 1 year, 2-year and 3-year real growth rates            |
| Credit to HHs as % of GDP                                    | 1 quarter, 1 year, 2-year and 3-year changes in percentage points |
| Credit to HHs                                                | 1 quarter, 1 year, 2-year and 3-year real growth rates            |
| Credit to HHs                                                | gap (400'000)                                                     |
| Credit to NFCs                                               | gap (400'000)                                                     |
| Loans to HHs for house purchase                              | 1 quarter, 1 year, 2-year and 3-year real growth rates            |
| NFPS Debt service ratio                                      | 1 quarter, 1 year, 2-year and 3-year changes in percentage points |
| HHs Debt service ratio                                       | 1 quarter, 1 year, 2-year and 3-year changes in percentage points |
| House price to income                                        | 1 quarter, 1 year, 2-year and 3-year changes in percentage points |
| RRE prices                                                   | 1 quarter, 1 year, 2-year and 3-year real growth rates            |
| RRE prices                                                   | gap (400'000)                                                     |
| Gross value added construction activities                    | 1 quarter, 1 year, 2-year and 3-year real growth rates            |
| Gross value added of construction and real estate activities | 1 quarter, 1 year, 2-year and 3-year real growth rates            |
| Share of GVA by construction and real estate activities      | 1 quarter, 1 year, 2-year and 3-year changes in percentage points |
| RRE investment                                               | 1 quarter, 1 year, 2-year and 3-year growth rates                 |
| RRE investment to GDP                                        | 1 quarter, 1 year, 2-year and 3-year real growth rates            |

# Univariate results in-sample

| Variable                                                      | Coefficient | AUROC | Category                              |
|---------------------------------------------------------------|-------------|-------|---------------------------------------|
| HH debt service ratio, 3-year change                          | 1.627***    | 0.901 | Cyclical credit and debt burden       |
| Credit to HH as a % of GDP, 3-year change                     | 0.548***    | 0.855 | Cyclical credit and debt burden       |
| RRE prices to income, 3-year change                           | 0.265***    | 0.850 | RRE prices                            |
| Credit to HHs, 3-year real growth                             | 0.0315**    | 0.822 | Cyclical credit and debt burden       |
| RRE prices, 3-year real growth                                | 0.147***    | 0.809 | RRE prices                            |
| Real RRE prices gap                                           | 0.0756***   | 0.787 | RRE prices                            |
| Real estate and construction GVA, 3 year growth               | 0.130***    | 0.770 | Construction and real estate activity |
| RRE investment, 3-year growth                                 | 0.0265***   | 0.763 | Construction and real estate activity |
| Credit to HHs as % GDP gap                                    | 0.222***    | 0.759 | Credit                                |
| RRE investment as % GDP, 3-year growth                        | 6.760***    | 0.746 | Construction and real estate activity |
| Share of GVA from construction and real estate, 3-year growth | 168.5***    | 0.717 | Construction and real estate activity |
| RRE prices to income                                          | 0.0361**    | 0.697 | RRE prices                            |
| HH debt service ratio                                         | 0.111**     | 0.661 | Structural credit and debt burden     |
| HH credit to GDP                                              | 0.0220**    | 0.658 | Structural credit and debt burden     |

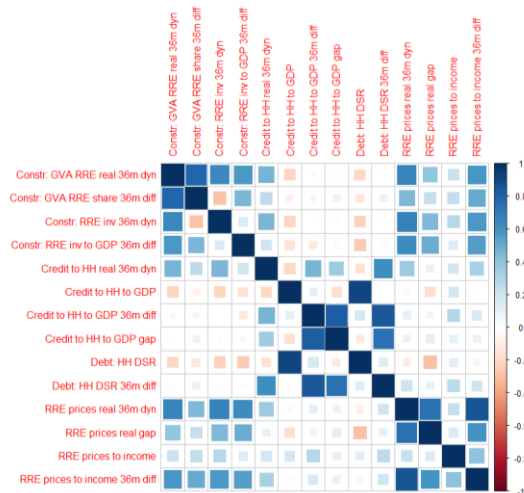

- In the univariate analysis we use all crises available for the different variables → we do not restrict the sample of variables to a common sample of crisis (as opposed to the multivariate)
- We see that:
  - Credit developments and debt burden variables for the HH sector perform (slightly) better than credit to NFPS
  - Transformations over longer horizons (36 months) perform better than over shorter horizons – persistence in the trends is relevant
- Univariate analysis is used to select the best performing variables for the multivariate analysis - we select several top variables from each 4 categories (on the basis of in-sample AUROC and statistical significance of coefficients)
- We do not consider similar transformations of the same variable (e.g. 1 credit to GDP change)

# Multivariate (I/II) – initial choices

- Limited data availability implies that we face a trade-off between more LHS and more RHS variables
- Multivariate analysis based on 7 crisis (including one in the 90s) and 14 RHS variables
- We have to consider high pair-wise correlations between variables for the multivariate analysis
- We estimate multivariate models on different combinations of 4 type of variables (including 1 variable per category)

## Correlations between variables selected in the univariate exercise

## Selection of variables

| Structural            | Cyclical                                  | RRE prices                          | Construction and real estate                                  |
|-----------------------|-------------------------------------------|-------------------------------------|---------------------------------------------------------------|
| Credit to HH as % GDP | HH debt service ratio, 3-year change      | RRE prices to income, 3-year change | Real estate and construction GVA, 3 year growth               |
| HH debt service ratio | Credit to HH as a % of GDP, 3-year change | RRE prices, 3-year real growth      | RRE investment, 3-year growth                                 |
|                       | Credit to HHs, 3-year real growth         | Real RRE prices gap                 | RRE investment as % GDP, 3-year change                        |
|                       | Credit to HHs as % GDP, gap               | RRE prices to income                | Share of GVA from construction and real estate, 3-year change |

- Debt service ratio and the 3-year changes in the debt service ratio to HHs are the variables that exhibit the best performance in the multivariate setting
- However, credit, RRE prices and construction and real estate activity variables not always significant or not selected in the top specification
- To-do - one robustness check would be to re-run the multivariate analysis using variables selected on the basis of a univariate analysis using the same sample (data series length) as used for the multivariate analysis
- To-do – Aggregate the model results in an index

# Key takeaways and way forward

- EWM exercise aims at detecting vulnerable state pre-RRE-related systemic banking crises
  - High AUROC in-sample
  - Top variables relate to credit developments, debt burden and house prices
  - Transformations over longer horizons (36 months) perform better than over shorter horizons
- Next steps and key challenges:
  - Limited data availability in our macroprudential database imply that we lose many observations (i.e. crises) – should we try to improve the data availability by using other sources (OECD or national)?
  - Current exercise is only in-sample – out-of-sample will be very challenging due to number of crises, but we could exclude one crises at a time and test out-of-sample properties when trying to detect this vulnerable state
  - Aggregation of best performing variables in an index using weights from the multivariate models and show its early warning properties
  - Possible overlap / correlation with the broader SRI as a key challenge to be addressed

# Aggregation of results

- The RRE-index could be a weighted average of the individual “normalised” top performing indicators

$$RRE\ index_{i,t} = \sum_{j=1}^K \omega^j \cdot \tilde{x}_{i,t}^j$$

$$\tilde{x}_{i,t}^j = (x_{i,t}^j - x_M^j) / \bar{x}_{IQR}^j$$

## Weights

- Common weights across countries and time
- Weights chosen to optimise early warning properties of the SRI

## Normalisation

- Common normalisation for all countries based on pooled median and IQR
- Normalisation provides for better interpretation of RRE index units and weights
- Normalisation does not affect the index properties compared to using raw data
